

Scour Development Around Offshore Wind Turbine Foundation: Field Measurement & Analysis

Figen H. Dixen, Jan Pedersen, Jesper Fris Dahl
DONG Energy, Wind Power

Martin Dixen
DHI, Ports and Offshore Technology

Outline of Presentation

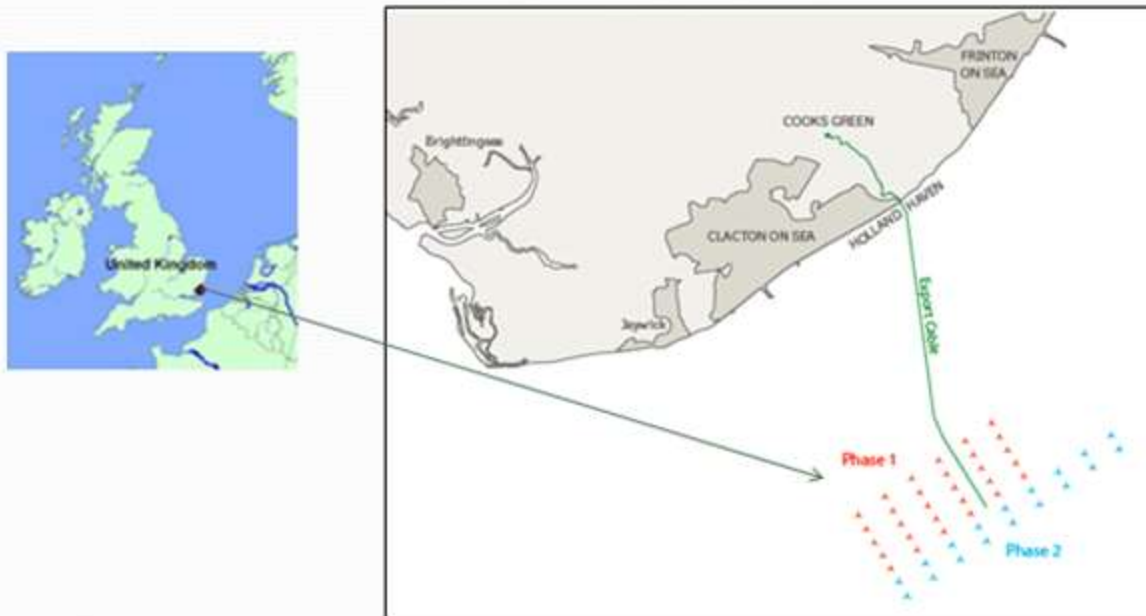

- Motivation
- Site location
- Monitoring set-up
- Environmental conditions
- Measurement results
- Mathematical model
- Comparison of the model with field data
- Conclusions

MOTIVATION

- To investigate the spatial and temporal variability of scouring
- Site specific validation of how much variation in scour depth can be expected
- Compared with the results of mathematical model to see how well that model captured the variation.

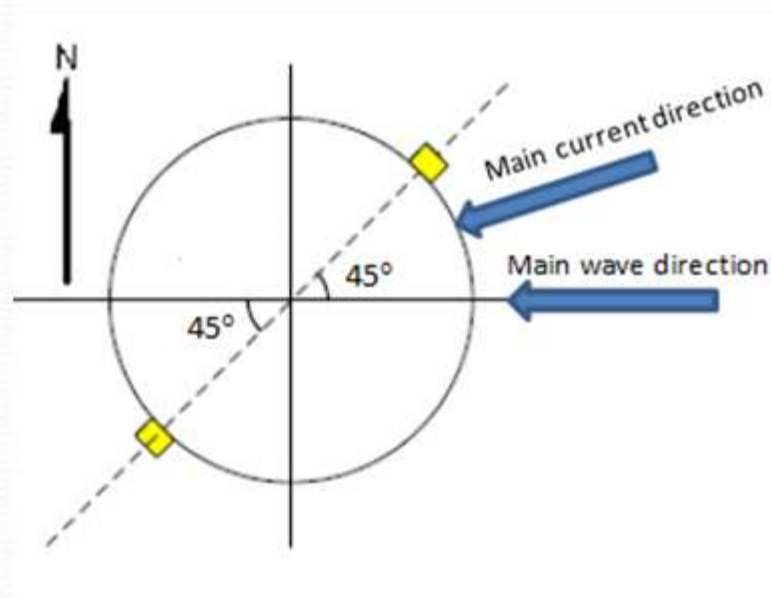

GUNFLEET SANDS 1 & 2

Measurement setup

Environmental conditions

DONG
energy

- **Wind Turbine Foundation**

- Pile diameter : 4.7 m

- **Soil Properties**

- Non-cohesive
 - Median grain diameter 0.2 mm

- **Environmental Condition**

- For the observation period:
 - Water level =11.4 MSL
 - Wave conditions $H_{s_{max}}=2.6$ m $T_p=8.3$ s
 - $U_{c_{max}} = 1.1$ m/s

Measured scour depths

Figure 4 : Spatial variation of scour depth. — Start of measurements, — End of measurements

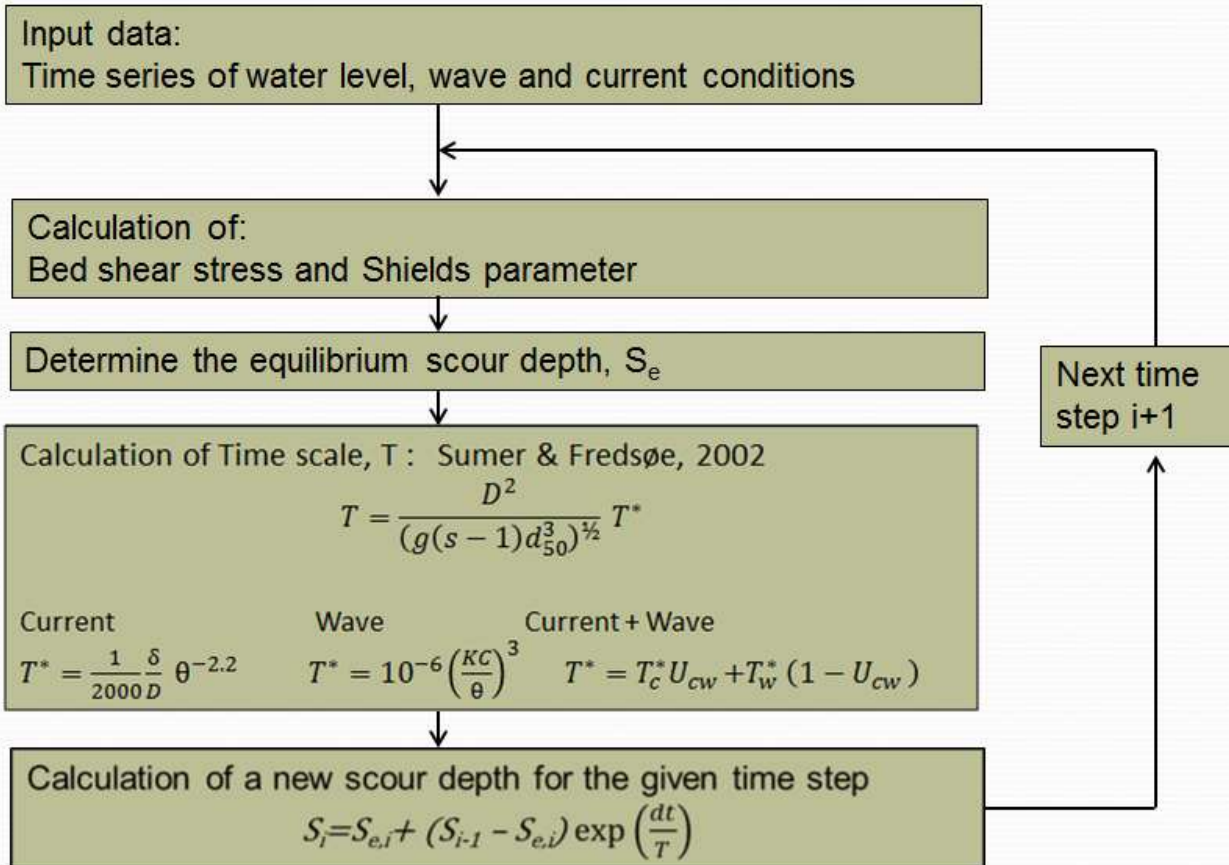

Mathematical model

Discretisation has been realized in the following way

$$S(t) = S_e \left(1 - \exp\left(-\frac{t}{T}\right) \right) \quad \text{Whitehouse, 1998}$$

$$S_i = S_{e,i} + (S_{i-1} - S_{e,i}) \exp\left(-\frac{dt}{T}\right)$$

Where the equilibrium scour depth of each time step $S_{e,i}$, is taken as the S_e corresponding to the environmental condition given in that particular time step.

Comparison

DONG
energy

Tuned model

Conclusions

- The maximum depth of scour observed during the measurement period is $S/D=1.7$.
- Scour depth increased despite of wave action and tidal reversal during the 6 months of measurement period.
- Assuming the backfilling rate as 10 times the scouring rate, the time development of scour has been predicted reasonably by using a relative simple mathematical model.

Thank you
